

# **Catalytic Production of Hydrogen, Fuels and Chemicals from Biomass- derived Oxygenated Hydrocarbons**

James A. Dumesic  
Department of Chemical & Biological Engineering  
University of Wisconsin  
Madison, WI 53706

# Motivation: oil in every day life

“Oil is the blood of today’s society”

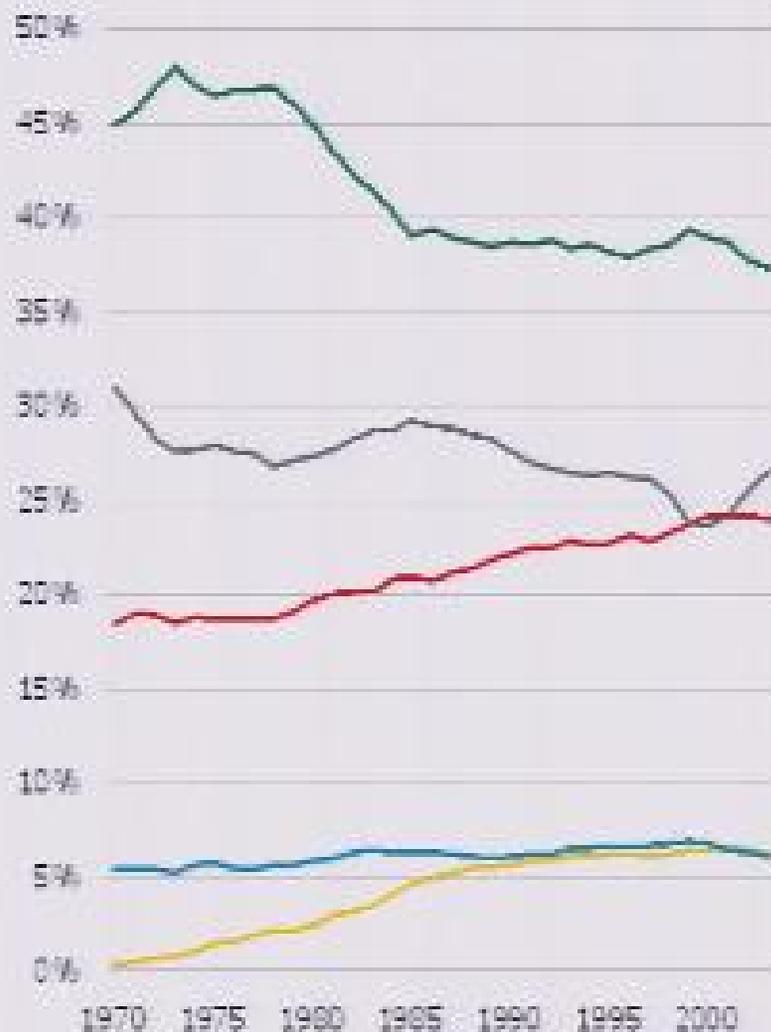

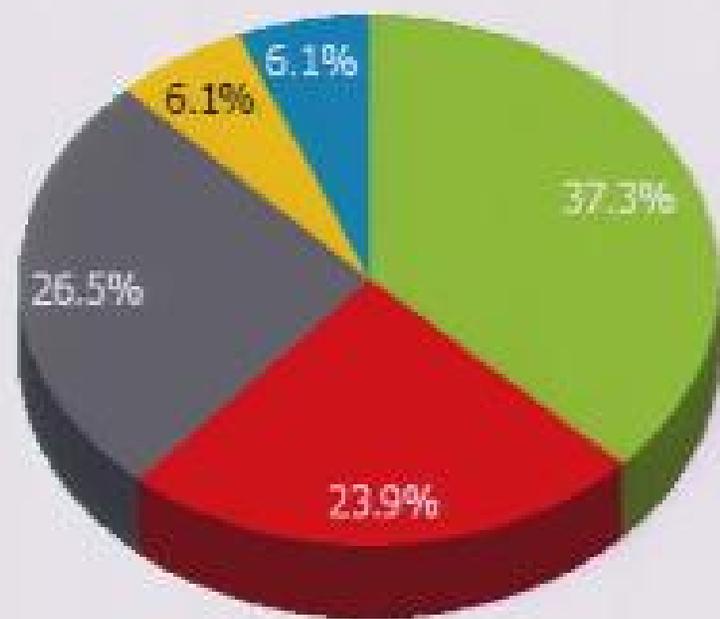

“Demand for petroleum products in the United States averaged 19.7 million barrels per day in 2004. This represents about 3 gallons of petroleum each day for every person in the country” (DOE annual report 2004)

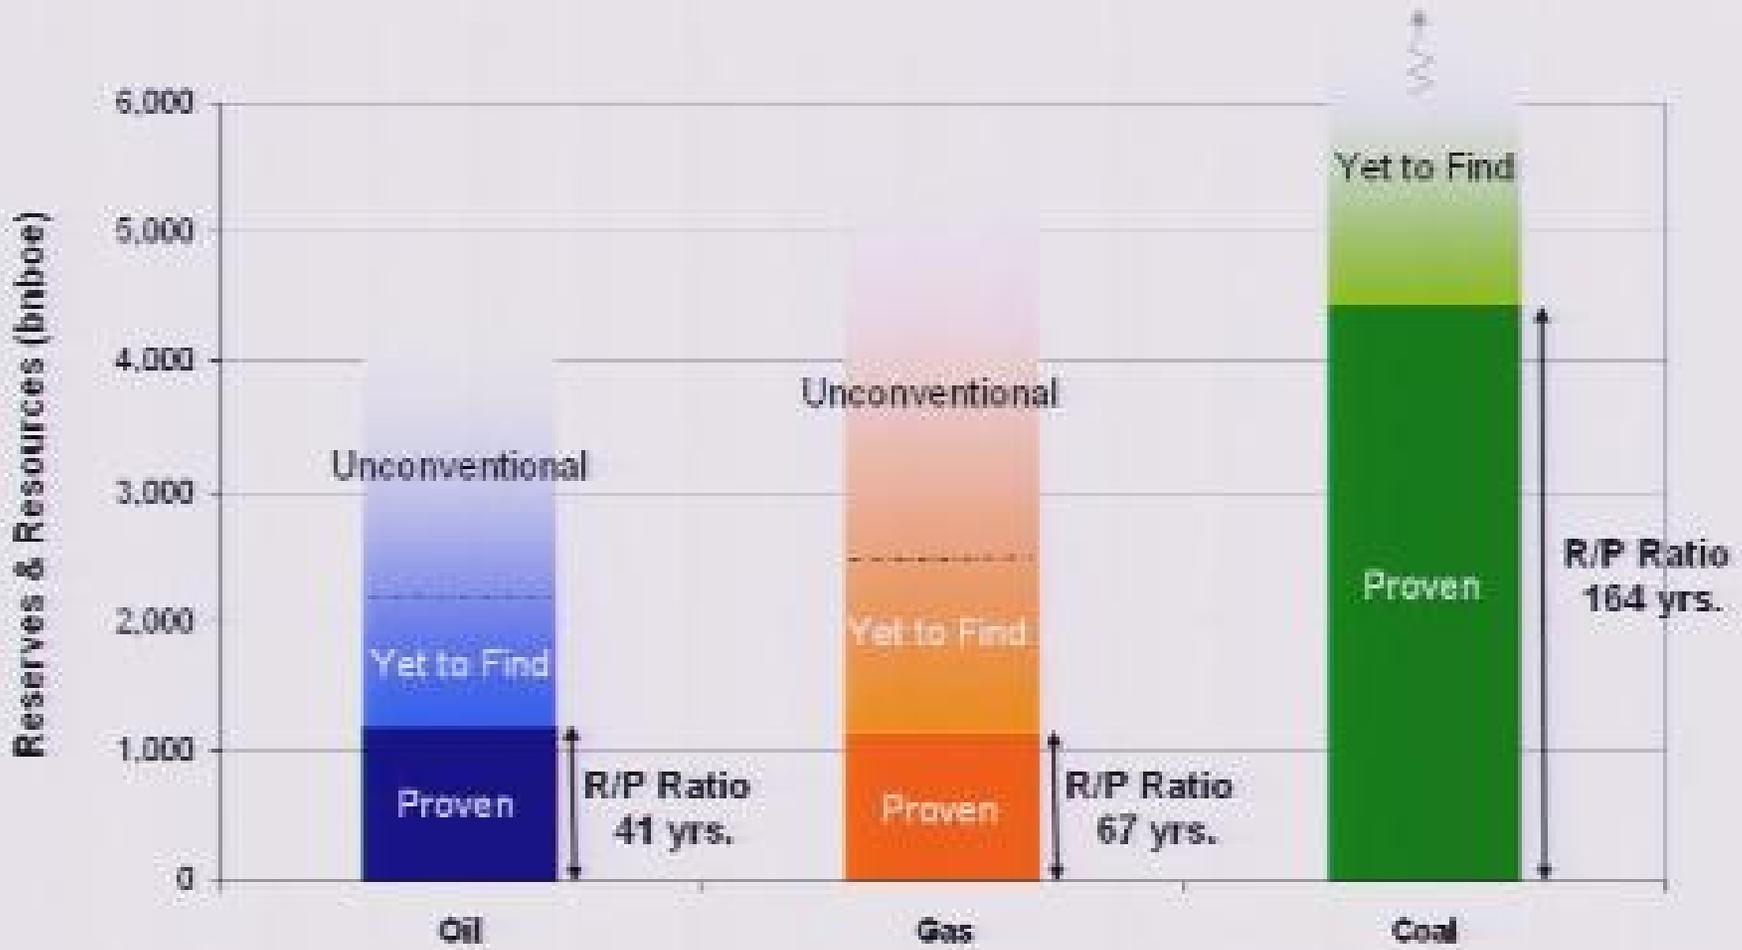

# current and historical global energy mix

Current global energy supply is dominated by fossil fuels – oil has been the largest component of the energy mix for many decades; gas has grown strongly since the 1970's; coal has been growing in the last four years; hydro is constant and nuclear has plateaued

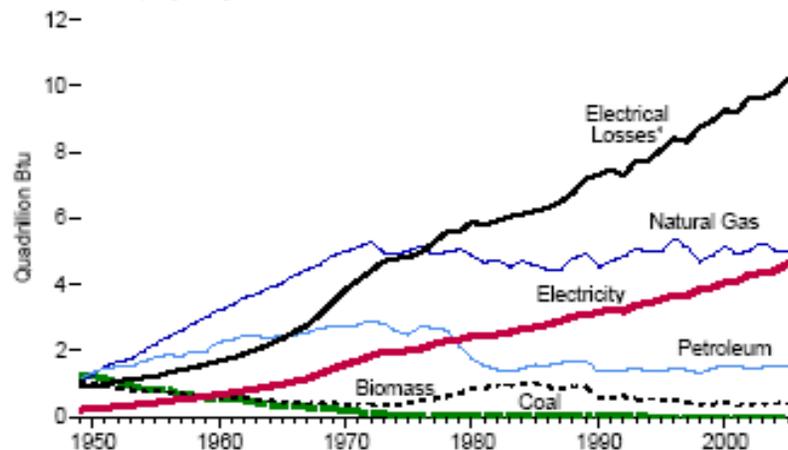

# substantial global fossil resources

Source: World Energy Assessment 2001; HIS; WoodMackenzie; BP Stat Review 2005; BP estimates

# U.S. Energy Consumption: End-Use

Residential, By Major Source

\* Electrical system energy losses associated with the generation, transmission, and distribution of energy in the form of electricity.

Note: Because vertical scales differ, graphs should not be compared.  
Sources: Tables 2.1b-2.1e.

# Biomass Potential

- $1.3 \times 10^9$  (billion) dry tons per year (U.S.)
- Equivalent to  $3.5 \times 10^9$  barrels of oil (boe)
- $1 \text{ boe} = 5.8 \times 10^6$  (million) BTU =  $6.1 \times 10^9 \text{ J}$
- Equivalent to  $20 \times 10^{15}$  (quadrillion) BTU/year
- U.S. energy consumption =  $140 \times 10^{15}$  BTU/year
- **U.S. biomass potential = 15%**
- Global Biomass production =  $95 \times 10^{15}$  BTU/year
- Woody biomass production =  $40 \times 10^{15}$  BTU/year
- Global energy consumption =  $315 \times 10^{15}$  BTU/year
- **Global biomass potential = 30%**

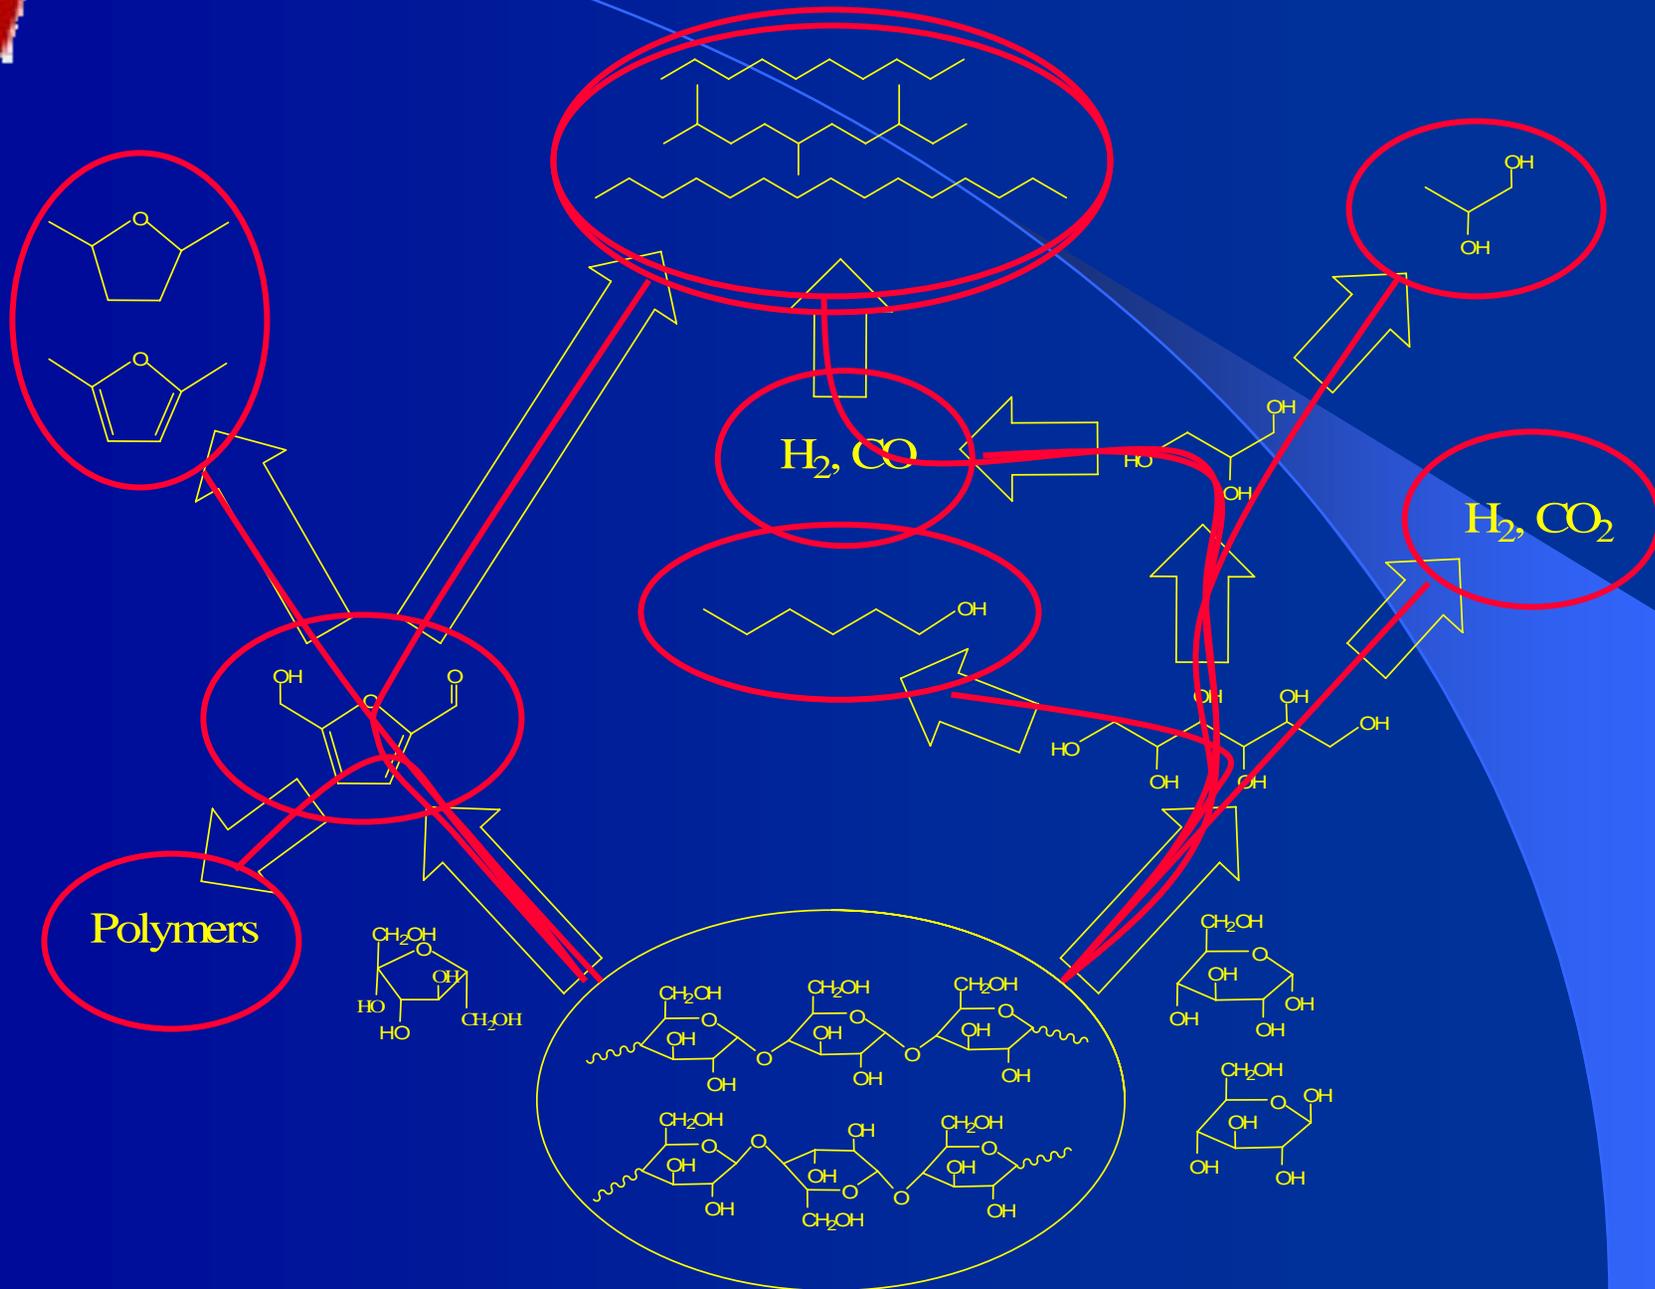

# Biomass – Transportation Sector

- Total energy consumed in U.S. = 140 quads
- Residential = 22 quads (16%)
- Commercial = 18 quads (13%)
- Industrial = 32 quads (23%)
- **Transportation = 28 quads (20%)**
- Electric Power = 41 quads (29%)
- **Biomass = 20 quads**
- **Biomass potential = 70% of transportation**

# Overview of Routes (at UW) for Biomass Conversion to Hydrogen, Fuels and Chemicals

# UW Routes to H<sub>2</sub>, Fuels & Chemicals

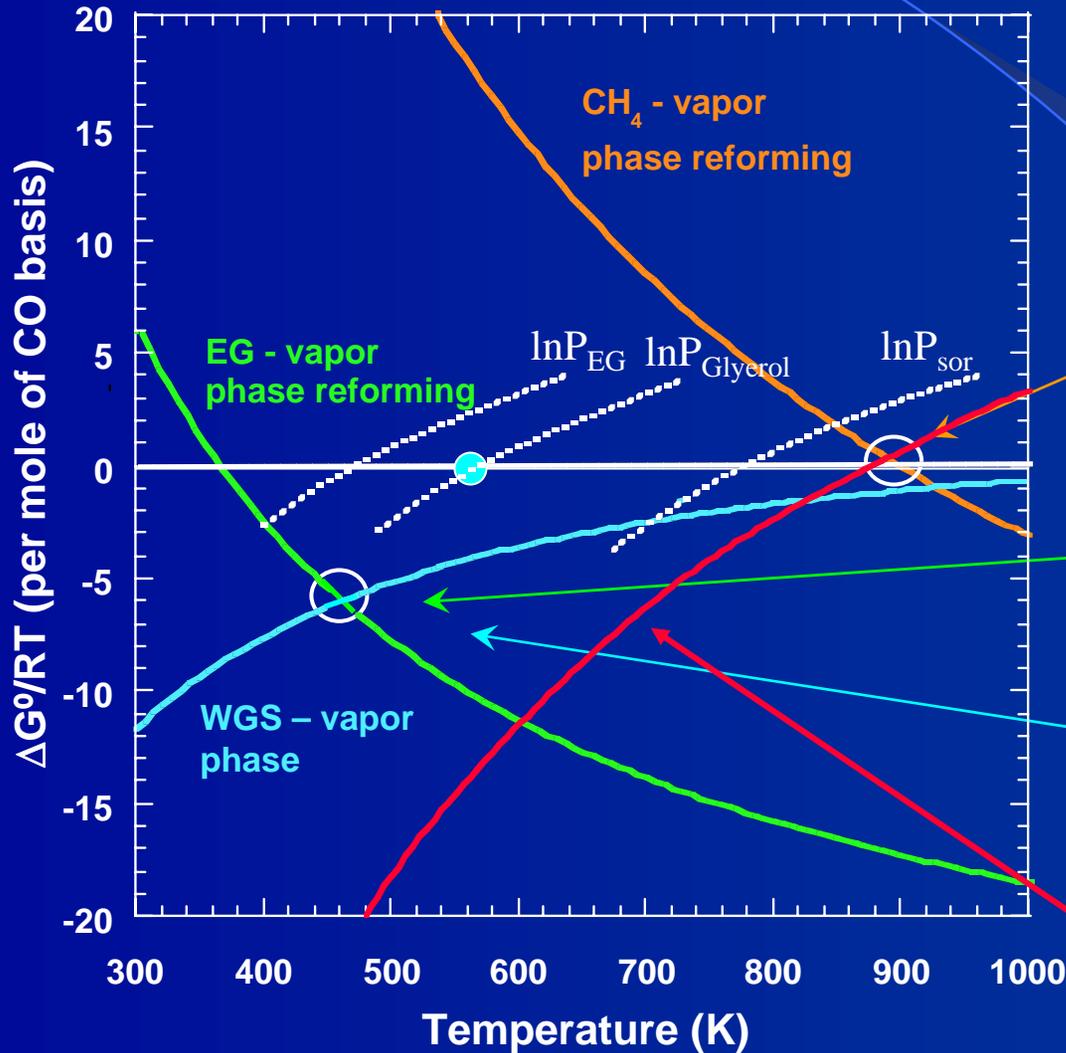

# Production of Hydrogen from Biomass-derived Carbohydrates

# Reforming Thermodynamics

**Methane reforming at high temperatures**

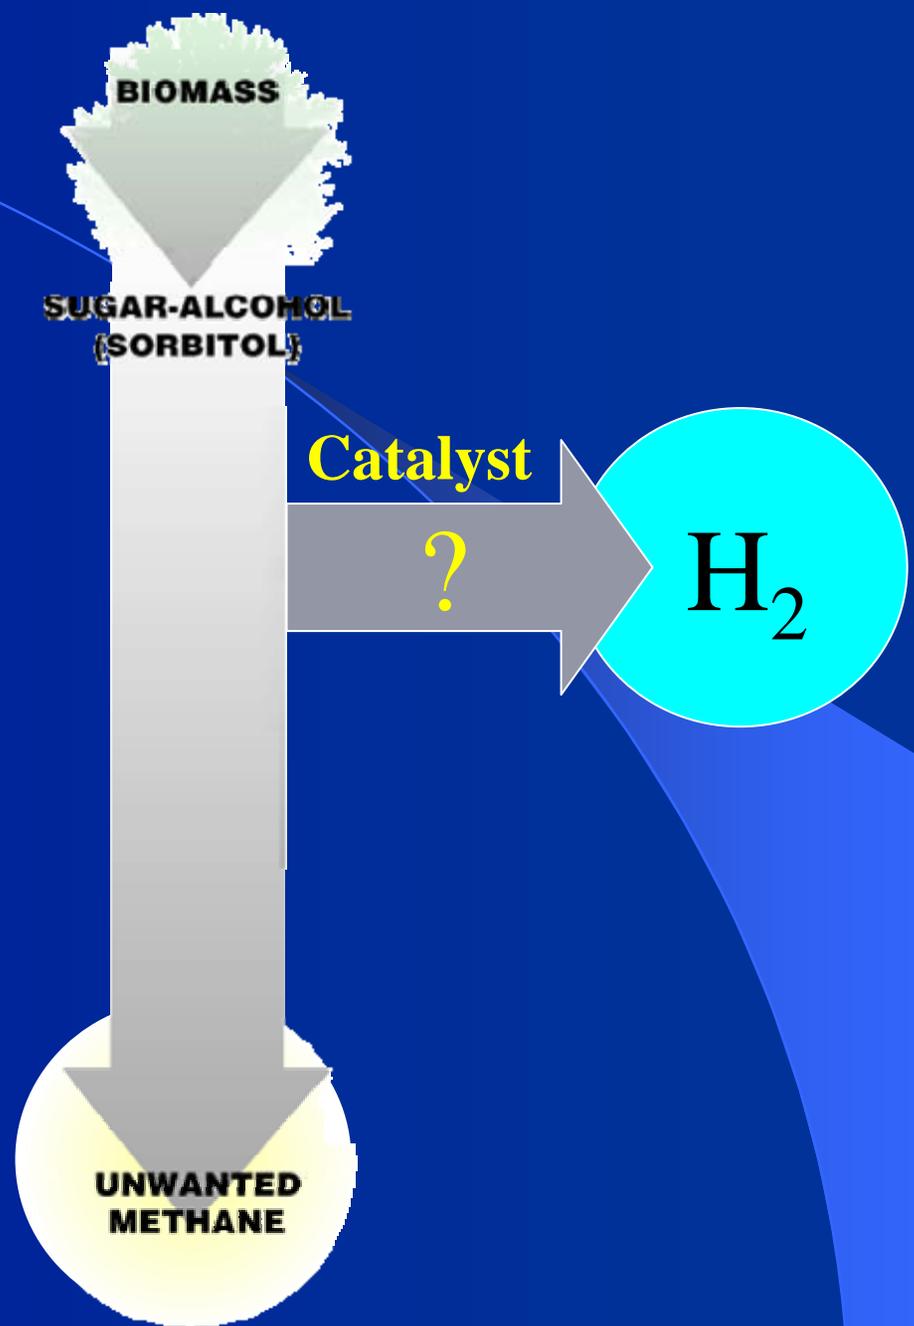

**Oxygenate reforming at low temperatures**

**Favorable Water-gas shift**

**Methanation favorable at low temperatures**

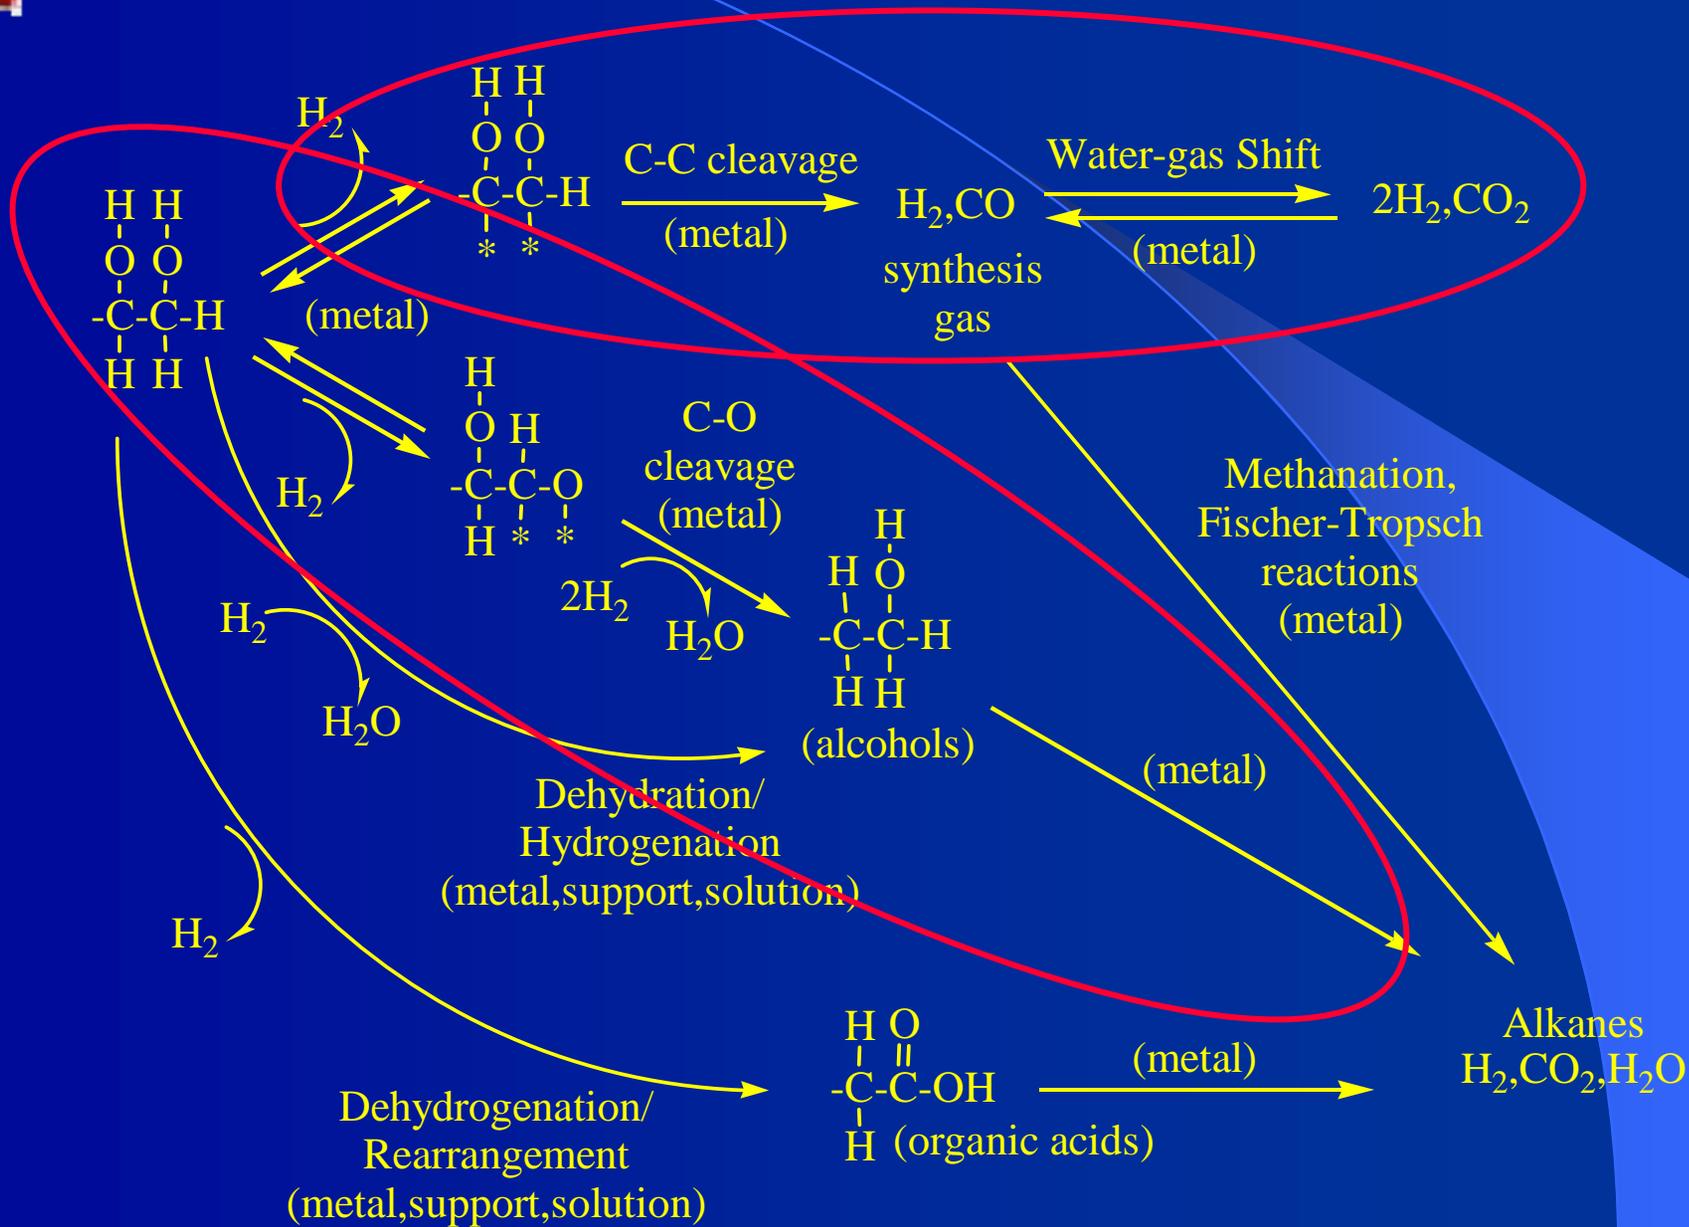

**The Challenge:**  
Can we find  
catalysts that  
produce  $H_2$   
versus  $CH_4$ ?

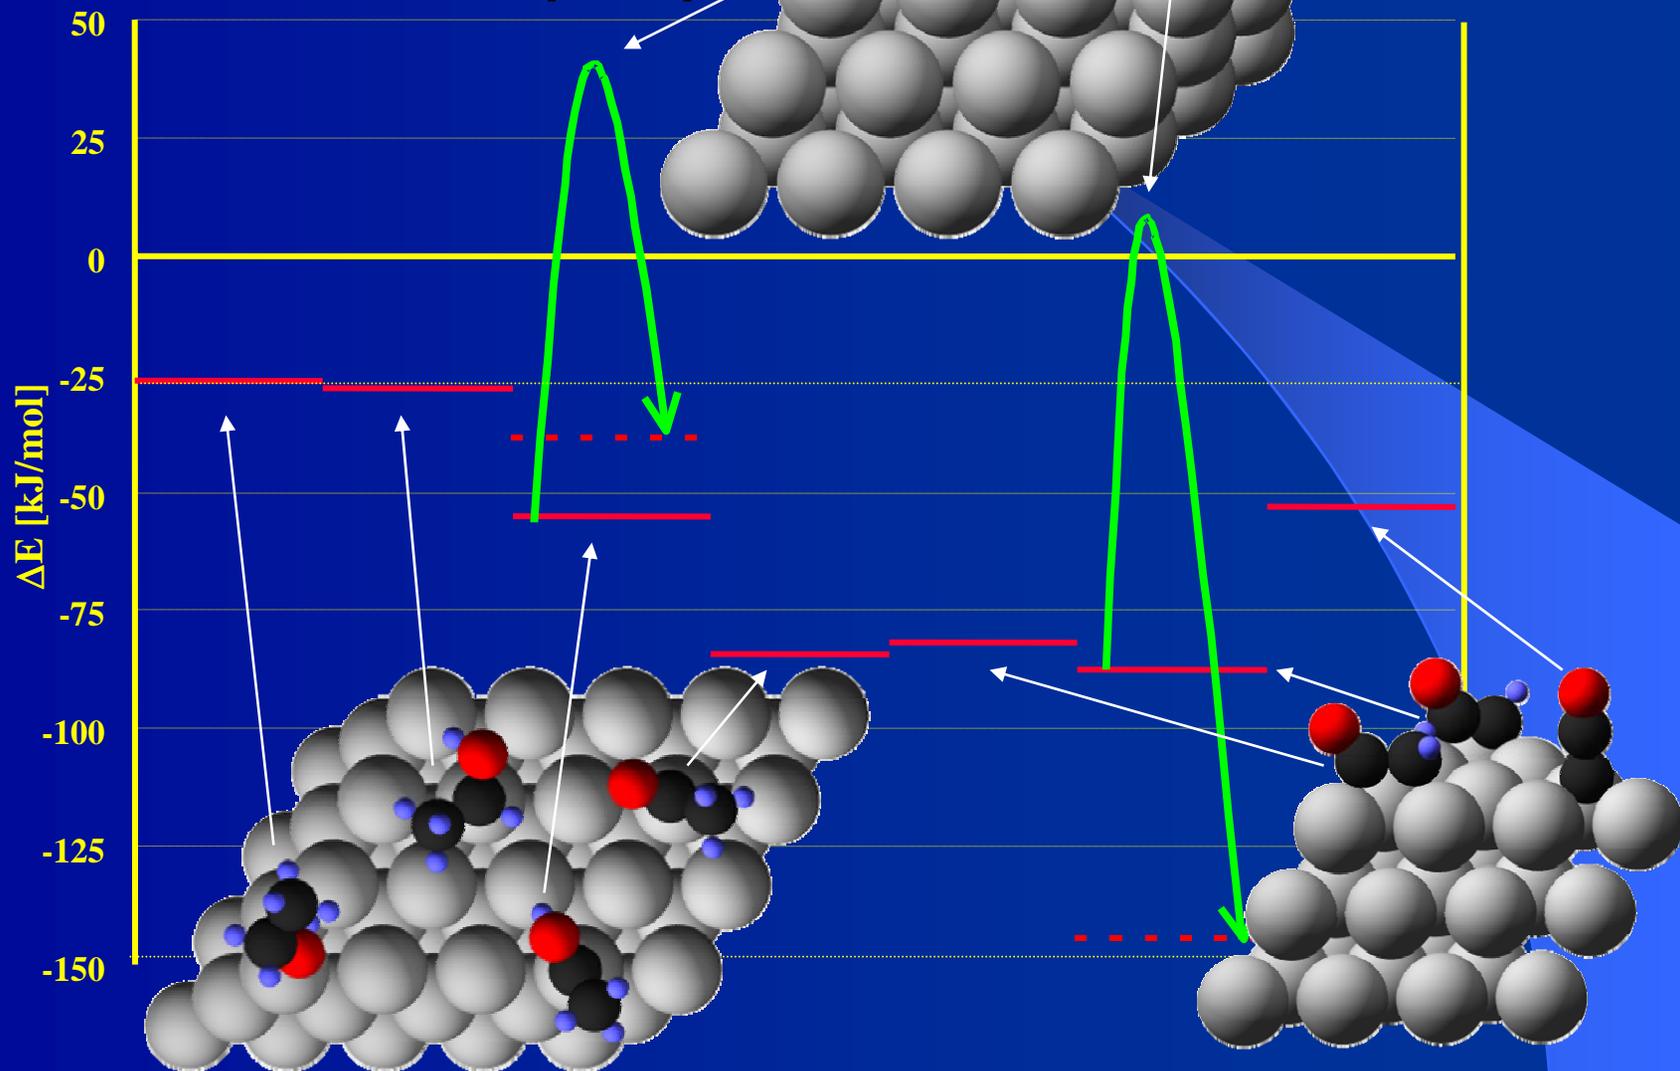

# Selectivity Challenges

# Potential Energy Diagram: Ethanol/Pt(111)

Alcala, Mavrikakis, Dumesic, *J. Catal.* **218**, 178 (2003)

# Reforming of Oxygenates over Supported Metal Catalysts

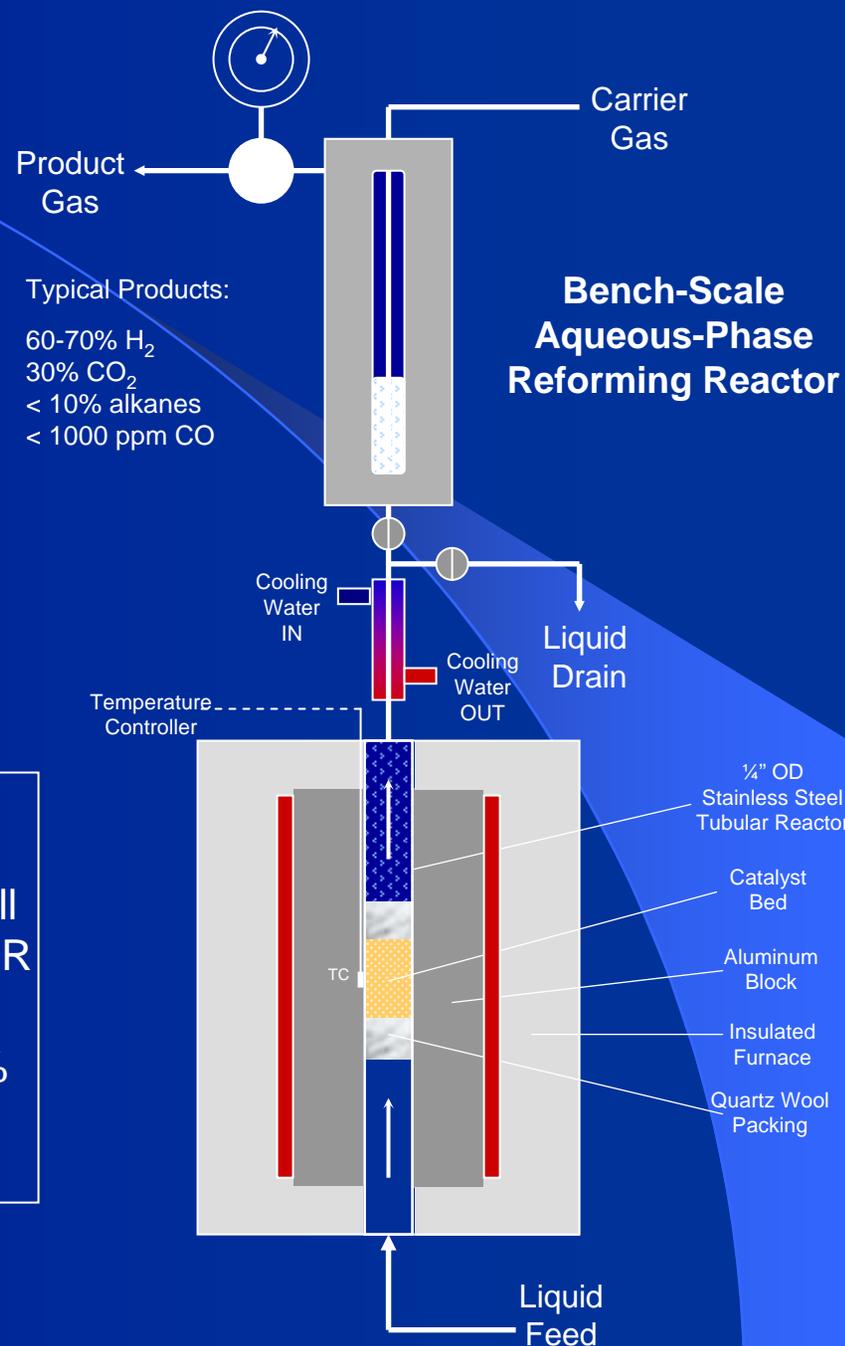

# Liquid Phase Kinetics

- Pressure maintained above bubblepoint pressure of feed at reaction temperature
- Differential reactor (verified kinetic control) or high-conversion operation
- Product analysis via GC, HPLC, TOC

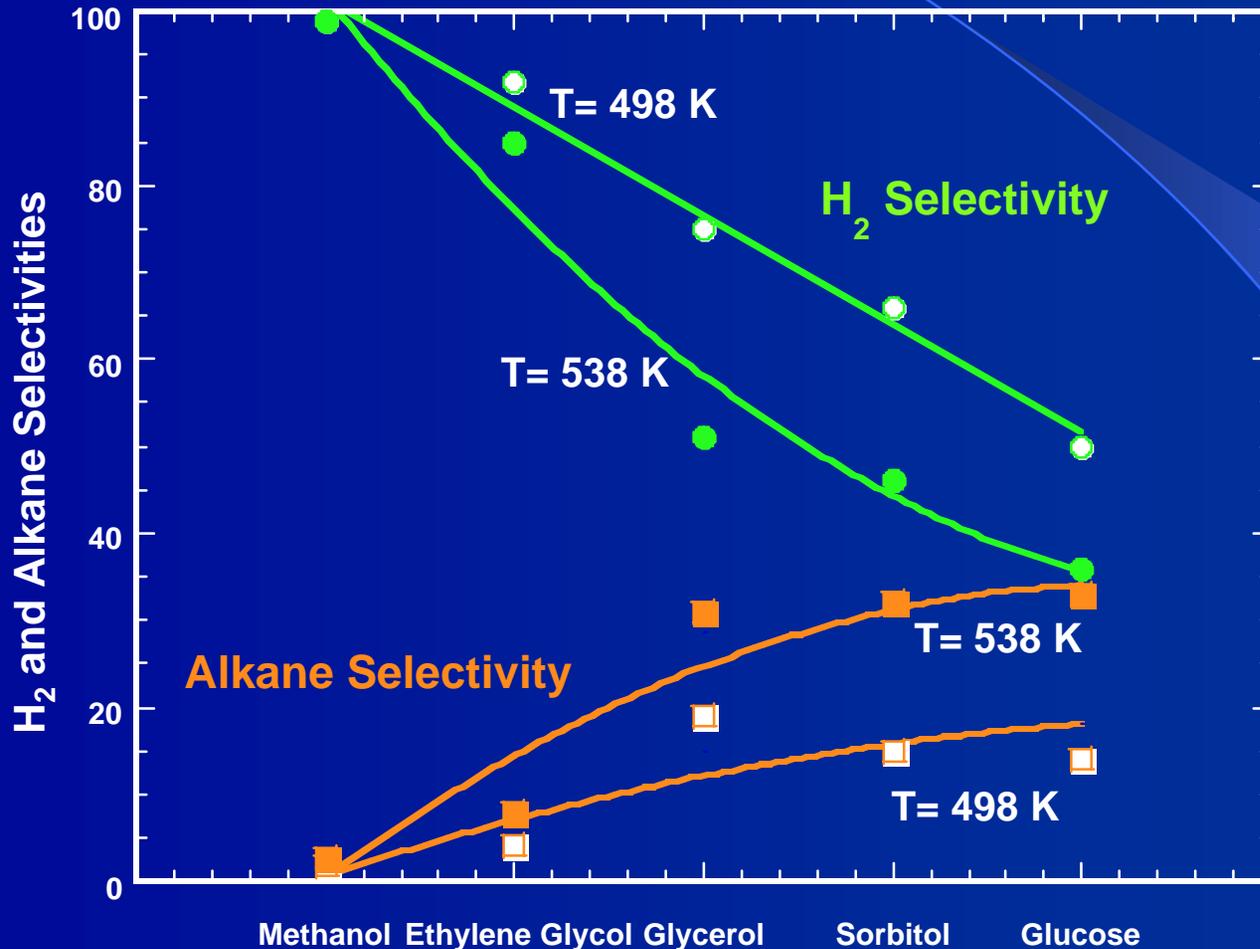

$$\text{H}_2 \text{ Selectivity} = \frac{\text{H}_2 \text{ Produced} \times 100\%}{\text{H}_2 \text{ that would be produced if all carbon products were from APR}}$$

$$\text{Alkane Selectivity} = \frac{\text{Carbon as alkanes} \times 100\%}{\text{Total carbon in products}}$$

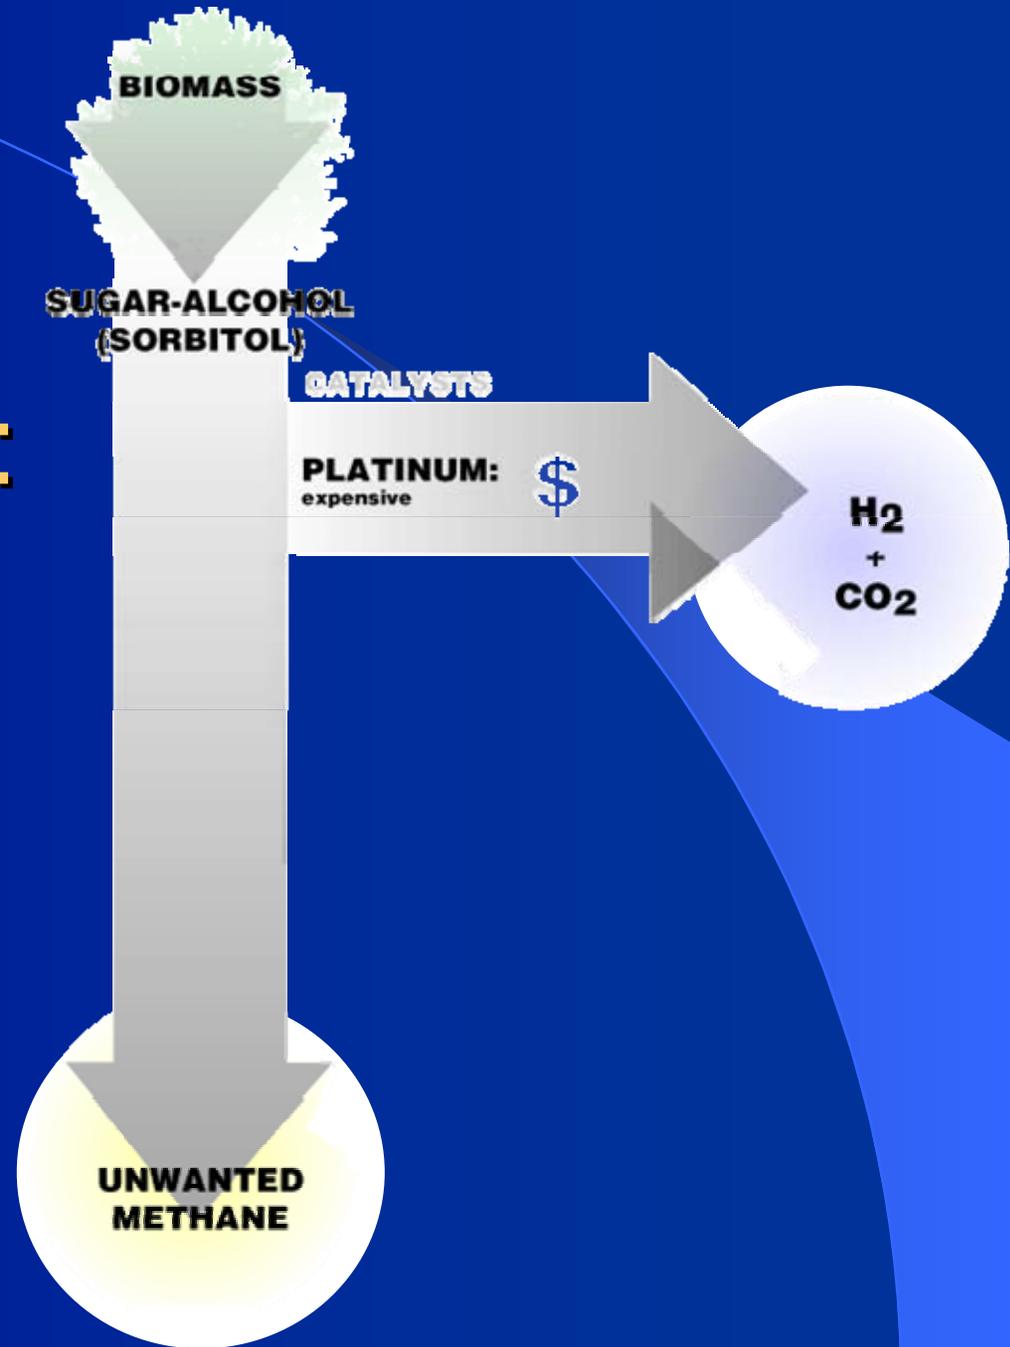

# Aqueous-phase Reforming of Oxygenates over Pt/Al<sub>2</sub>O<sub>3</sub>

- 1 wt% feed
- High Conversions
- Clean reaction – gas phase products
- Complete Carbon Balance

# Demonstration: Biomass to H<sub>2</sub> over Pt

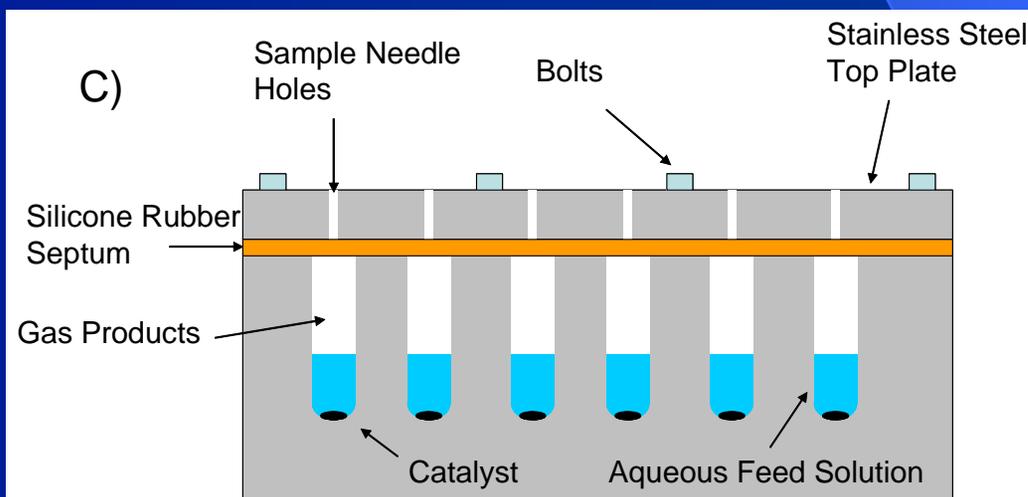

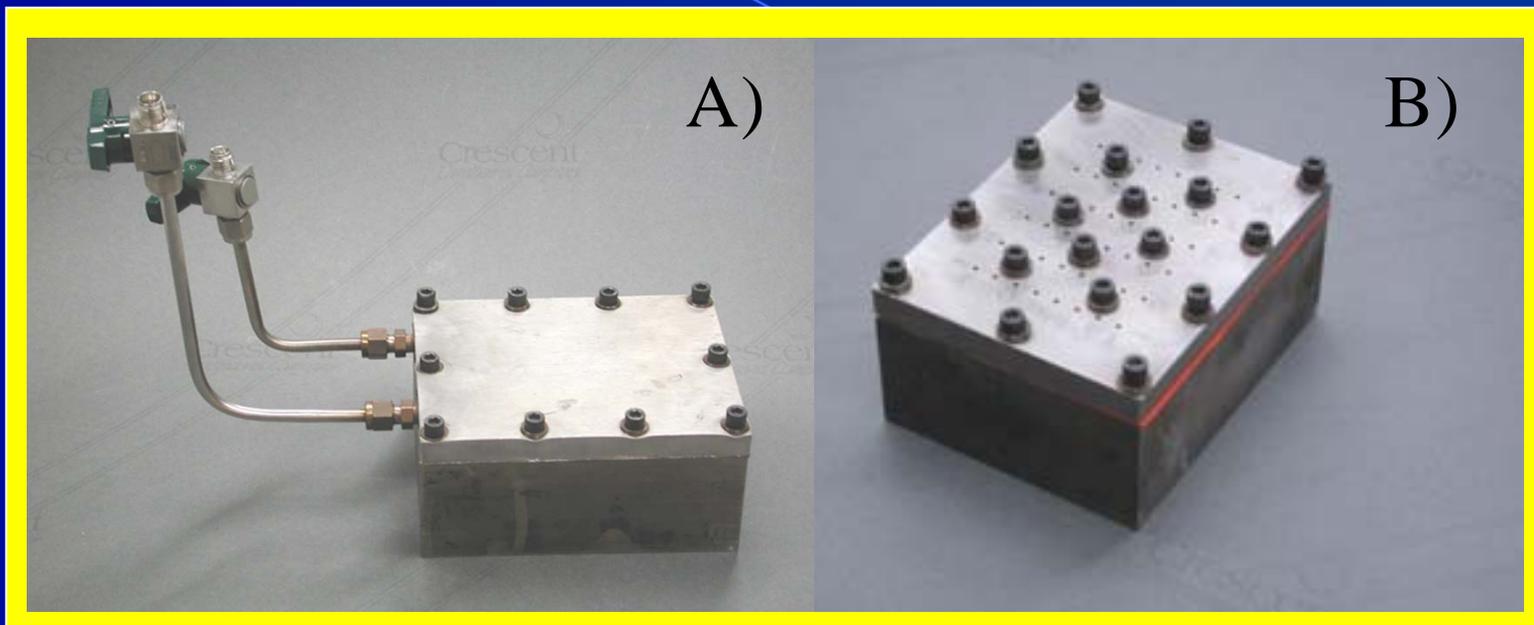

# Non-precious Metal Catalysts

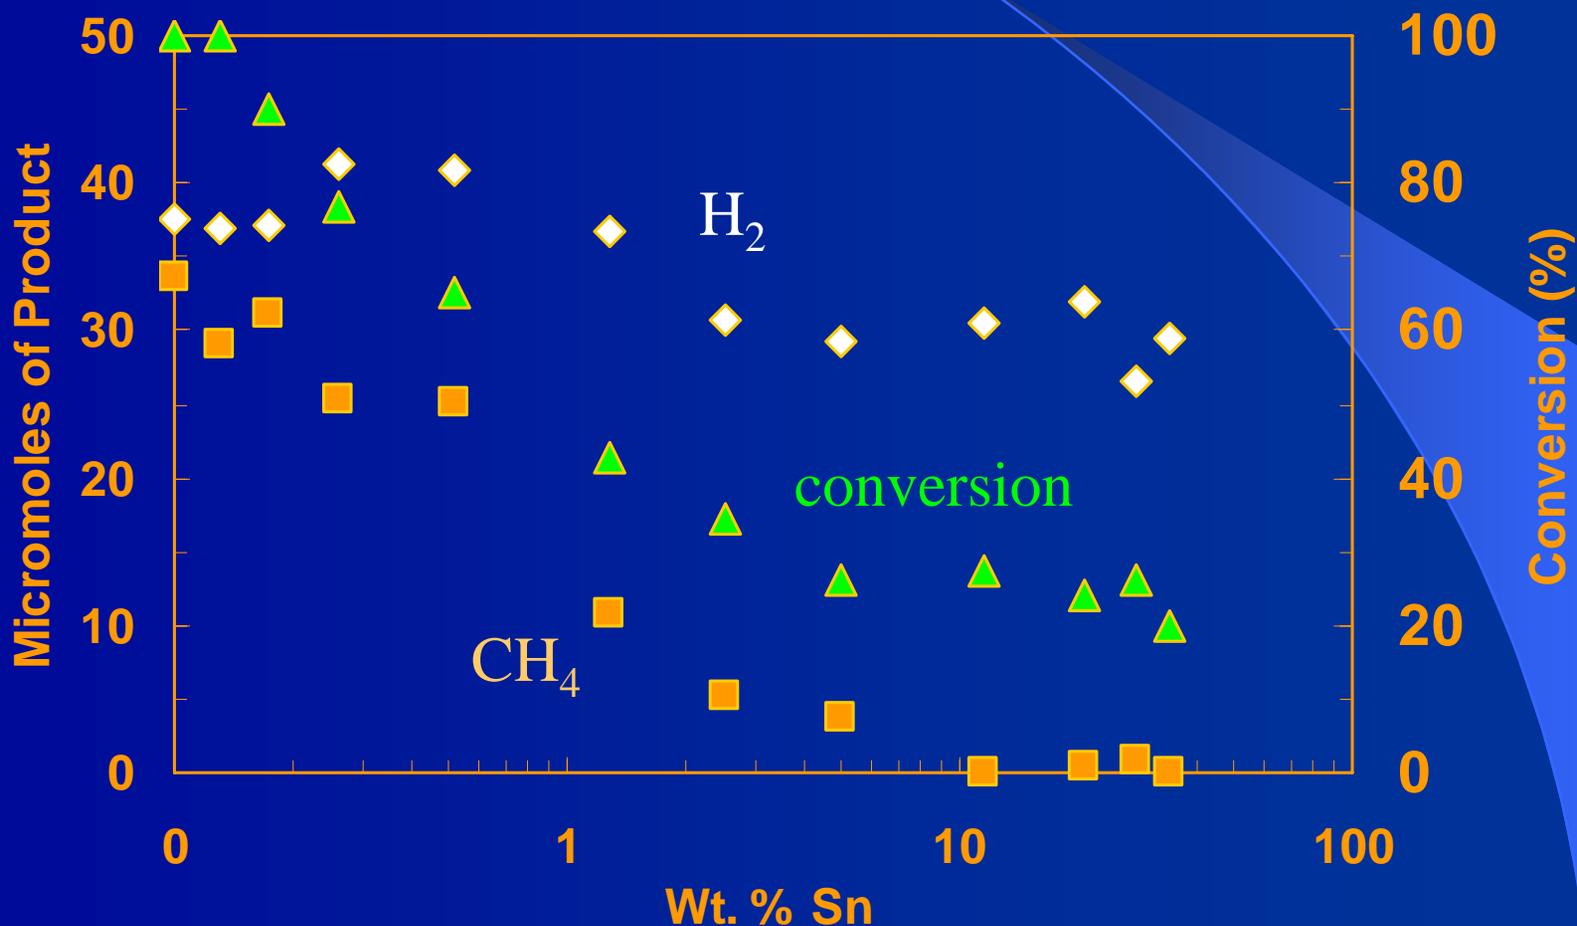

# High-Throughput Reactor

# High-Throughput Studies of Raney-NiSn

Huber, G.W.; Shabaker, J.W.; and Dumesic, J.A.; "Raney Ni-Sn Catalyst for H<sub>2</sub> from Biomass-Derived Hydrocarbons", *Science*, **300**, 2075-2077 (2003)

# EG-Reforming on Raney-NiSn: Packed-bed APR Reactor

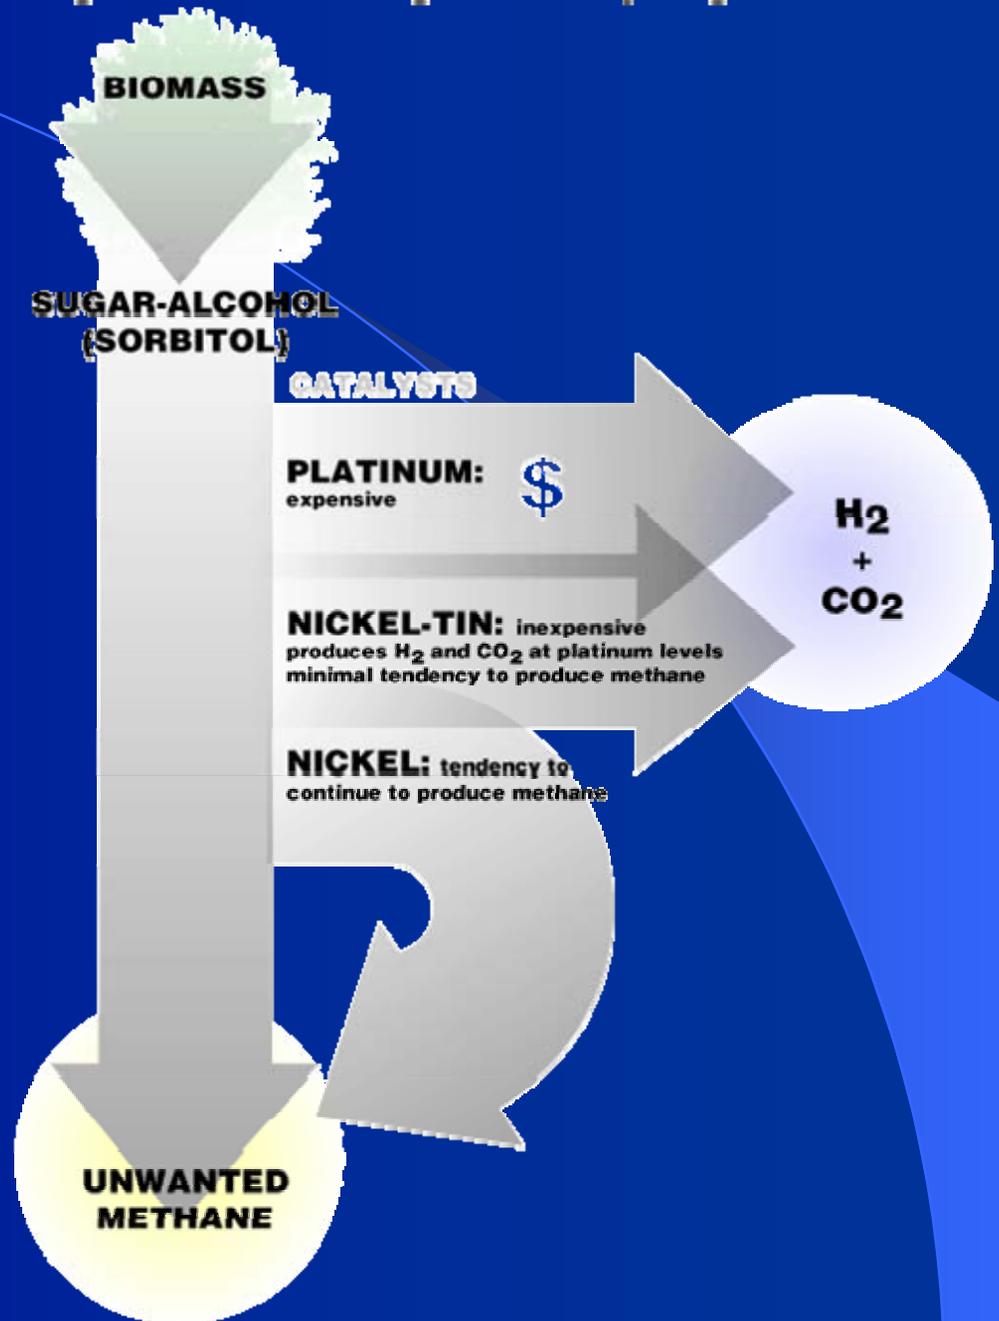

Catalyst	H <sub>2</sub> Selectivity %	Alkane Selectivity %	H <sub>2</sub> TOF min <sup>-1</sup>	CH <sub>4</sub> TOF min <sup>-1</sup>	H <sub>2</sub> Rate μmol cm <sup>-3</sup> min <sup>-1</sup>
Raney Ni	47	33	1.1	0.28	360
Raney Ni <sub>270</sub> Sn	57	27	1.4	0.23	430
Raney Ni <sub>14</sub> Sn	93	5	1.4	0.031	360
Pt/Al <sub>2</sub> O <sub>3</sub>	98	0	5.3	0	450

**Addition of Sn:** Improves H<sub>2</sub> selectivity  
Decreases CH<sub>4</sub> selectivity

Ni<sub>14</sub>Sn ~ Pt/Al<sub>2</sub>O<sub>3</sub>

## 10kWe APR/HICE Genset Specifications

(Preliminary)

### SuperNatural™ Gas Properties

Composition (by volume)

Hydrogen:	~30%
Methane:	~10%
Ethane:	~10%
Propane:	~10%
CO <sub>2</sub> :	~40%

Heating Value: 600 BTU/ft<sup>3</sup>

Pressure (exit of APR): 400-500 psig

### Feedstocks

- Glycerol (50% concentration)
- Sorbitol (future: late 2006)
- Glucose (future: late 2006)

### Integration

- Ford 1.6 liter, 4-Cylinder HCNG ICE/11.5 kW Genset
- Catalytic Burner can supply process heat
- ICE Exhaust heat integration
- Combined Heat and Power Mode (CHP)
- Optional PSA or Pd Membrane for pure hydrogen

### APR Weight & Dimensions

- 2 m Wide x 1 m Deep x 1.5 m High
- 725 Kg (without fuel)

### APR/HICE Performance at 10kWe output

APR Efficiency: 90%

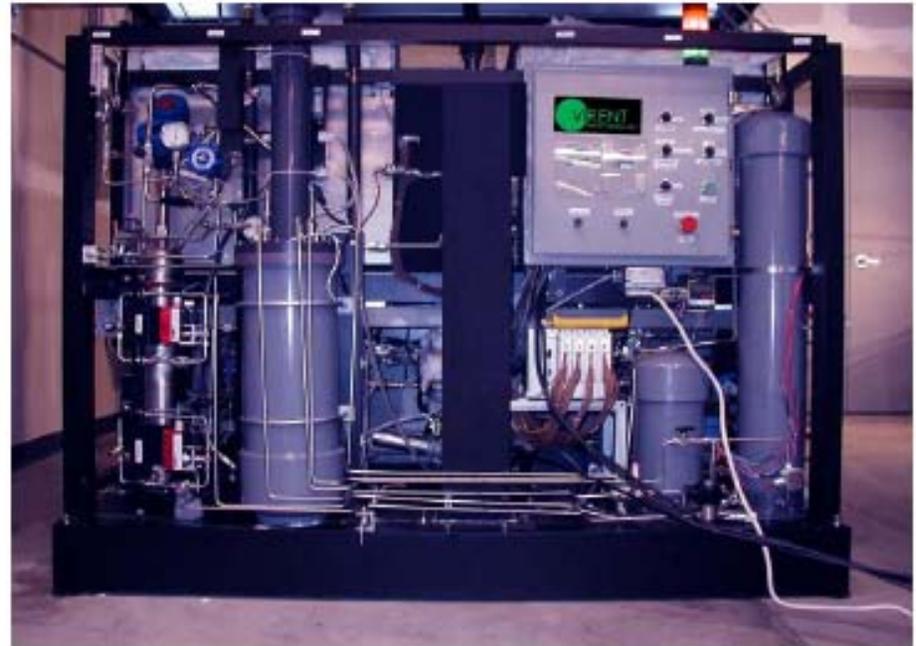

(LHV inputs/LHV outputs)

Feedstock Consumption: ~2.2 gal/hr

(Glycerol)

Gas flow rate into ICE: 90 liters/min

HICE Genset Efficiency: 32%

**APR/HICE System: Distributed Renewable Energy Generation.**

- **No Fossil Fuels Required.** Generate carbon neutral, high energy fuels from renewable widely available biomass-derived feedstocks
- **Untethered Operation.** The APR/HICE system can operate independently from the electrical grid or natural gas supplies.
- **Localized Production.** On-demand hydrogen and alkanes with low capital investment
- **Friendly Operating Conditions.** Significantly lower operating temperatures (240°C v. 800°C) allows for feedstock reformation and water-gas shift reaction to take place in one processing step.
- **Simple Purification.** Output pressures of APR hydrogen rich effluent (typically 10 to 50 bar) can be effectively purified, if desired, using either a pressure swing adsorption or palladium membrane technologies
- **Flexible.** Can produce multiple fuels and fuel blends tailored to the needs of the power conversion device.

# Vapor-phase Conversion of Glycerol to CO:H<sub>2</sub> Mixtures

# Sources of Glycerol

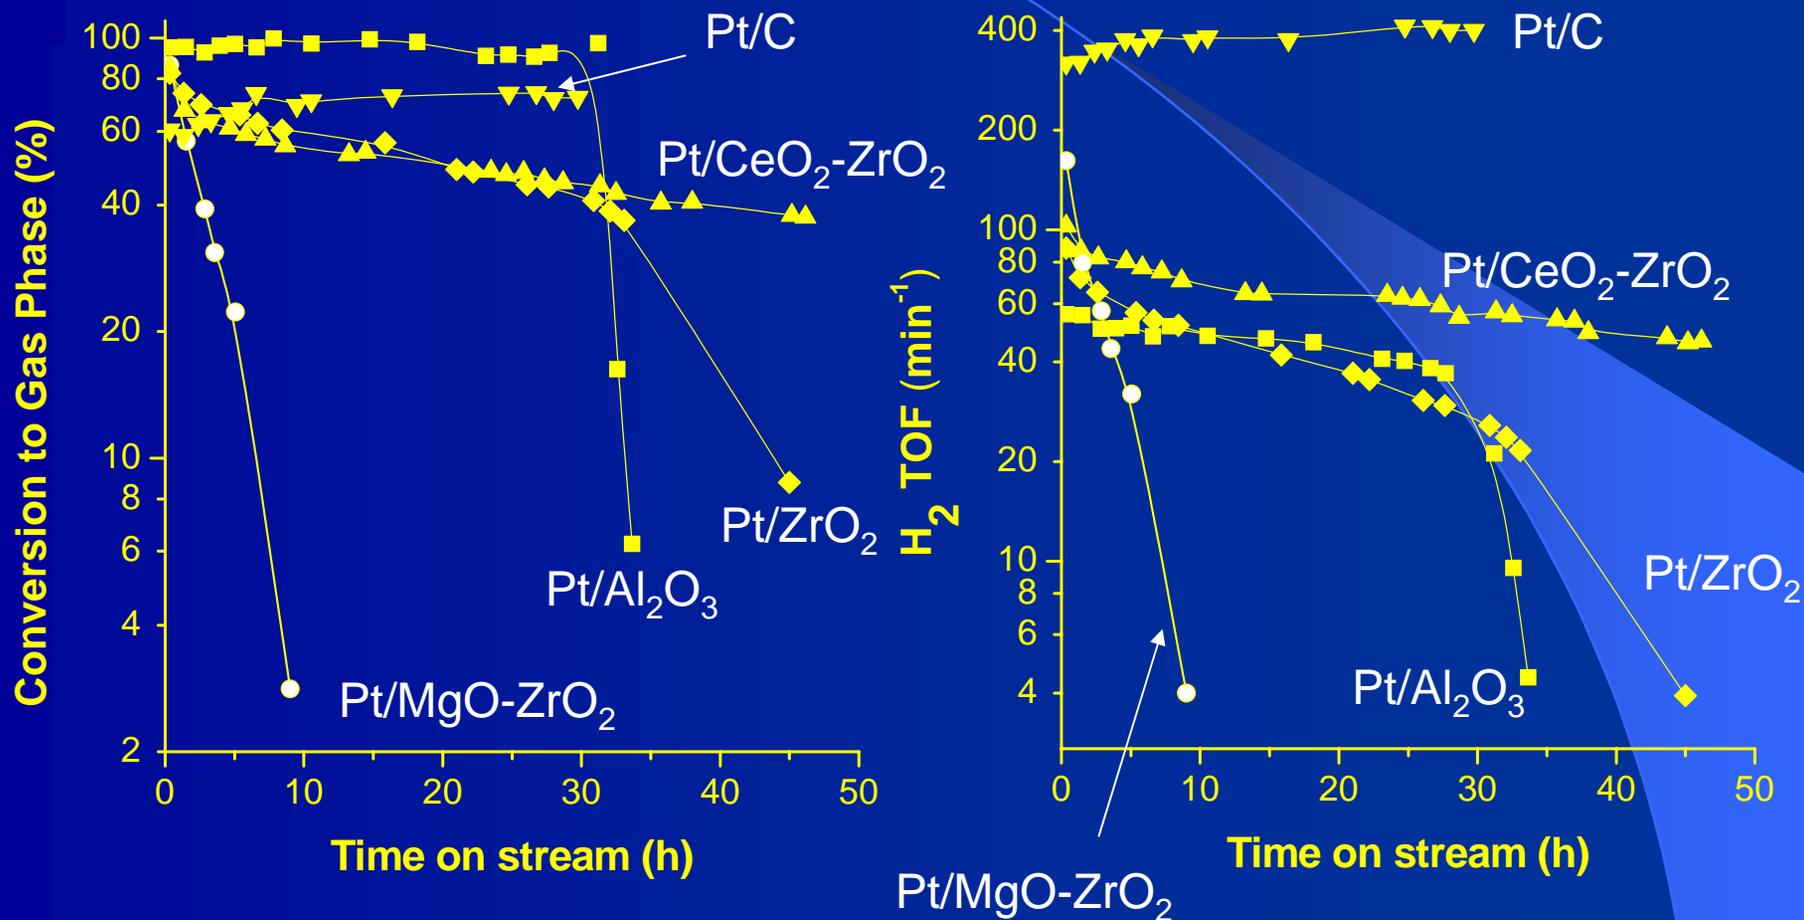

- By-product waste-stream from biodiesel production, i.e., trans-esterification of triglycerides, leading to ~80 wt% glycerol in water
- Glucose fermentation, leading to 25 wt% glycerol in water (compared to 5% for ethanol)
- Catalytic hydrogenolysis of xylitol and sorbitol ( $C_5$  and  $C_6$  sugar-alcohols)

# Glycerol Conversion to Synthesis Gas at 350°C

# Glycerol Reactivity (350°C)

# Coupling of Glycerol Conversion with Fischer-Tropsch Synthesis

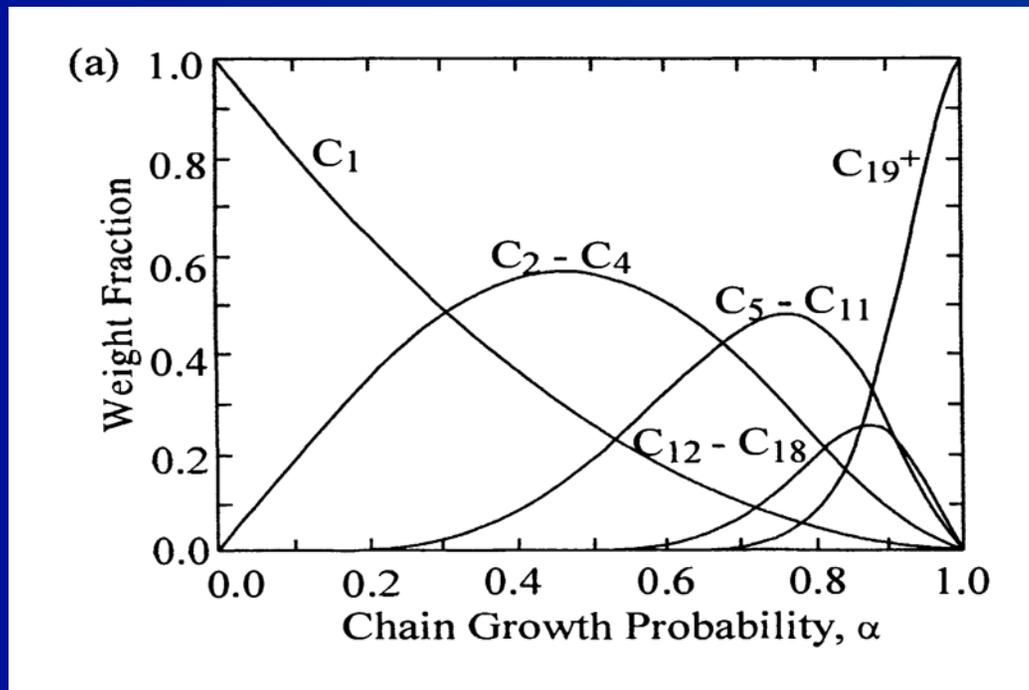

# Fischer-Tropsch Synthesis

Higher hydrocarbons from synthesis gas ( $\text{H}_2:\text{CO}$ )

Typical catalysts include: Fe, Co, and Ru

# Coupling Gasification & FT Synthesis

$$\frac{\Delta H_1}{\Delta H_c(\text{Gly})} = 24\%$$

$$\frac{\Delta H_5}{\Delta H_c(\text{Gly})} = -4\%$$

# Reforming Catalysts

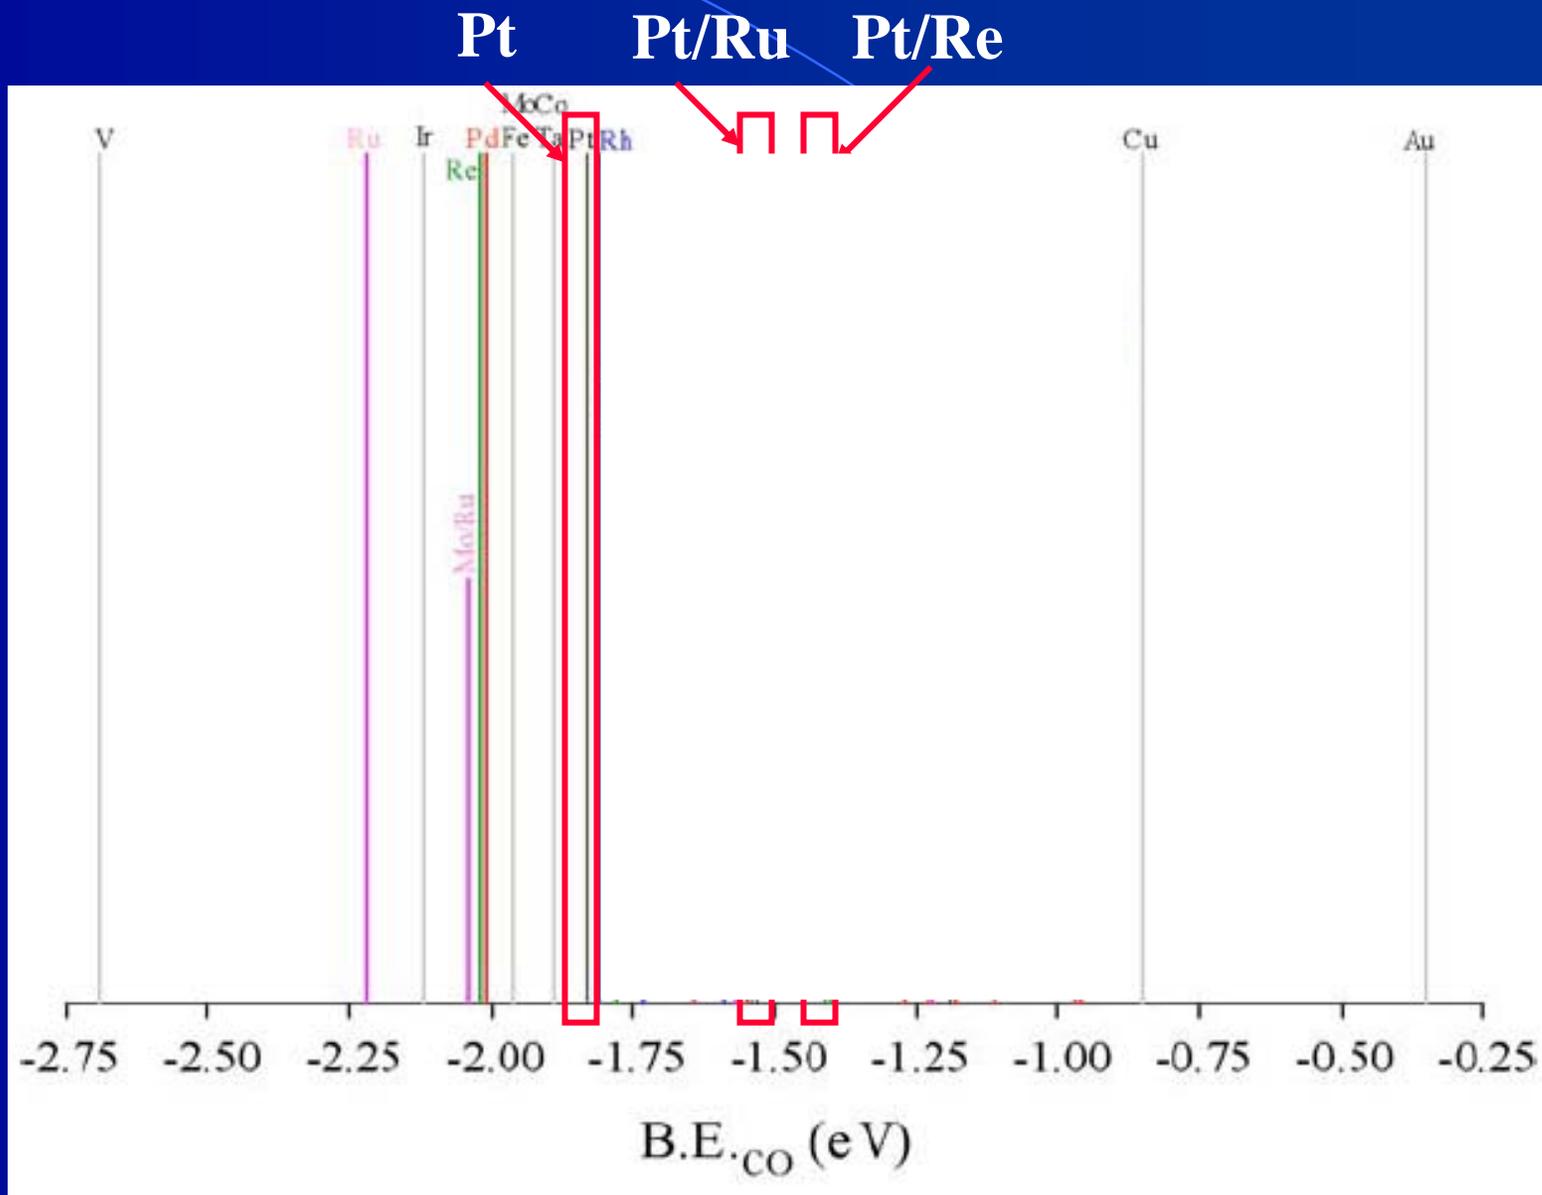

- Fischer-Tropsch synthesis typically carried out at 500 – 550 K (and 10 – 50 bar)
- Heat must flow from FT to reforming catalyst (Temperature for FT > T for reforming)
- Pt/C not active below ~573 K
  - $\Theta_{\text{CO}}$  increases as T decreases
  - Additives needed to lower adsorption energy of CO on Pt
- Surface alloys may be useful!!

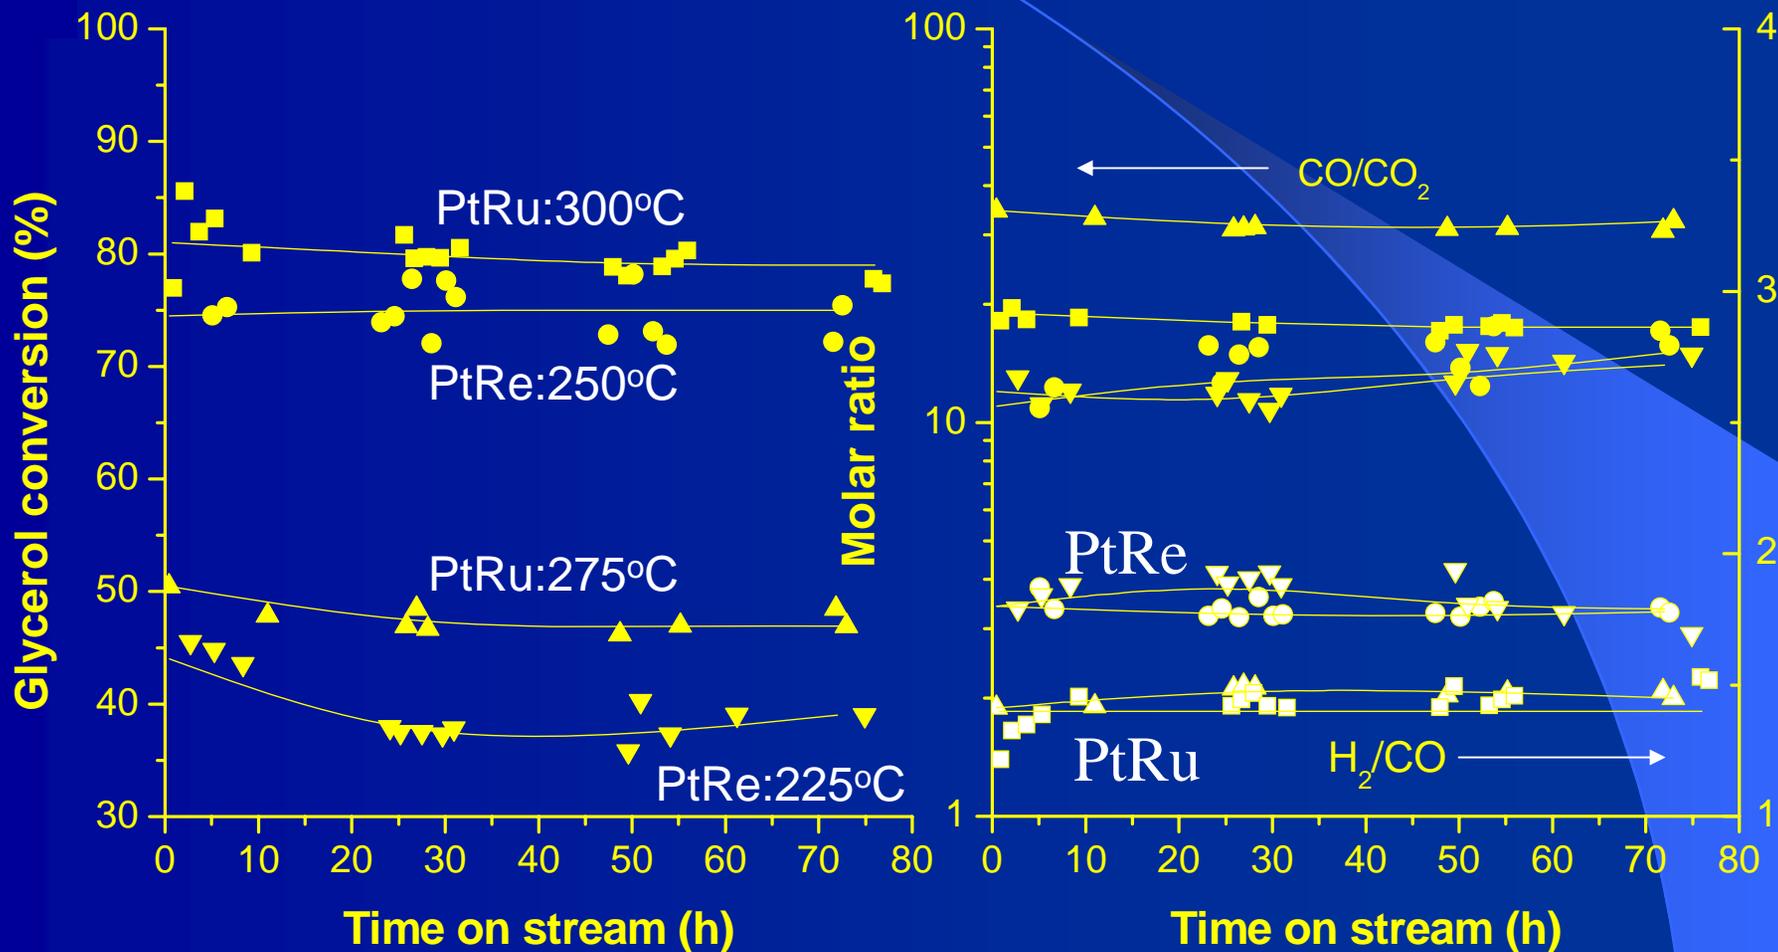

# CO Adsorption on Near Surface Alloys
